## ABSTRACT

Apparent molar volume ( $\phi_V$ ), molar refraction ( $R$ ), viscosity  $B$ -coefficient and adiabatic compressibility ( $\phi_K$ ) of some bio-active solutes such as glycine, L-alanine, and L-valine have been measured in 0.01, 0.03, 0.05 mol dm<sup>-3</sup> aqueous barium nitrate solutions at 298.15 K. Masson equation was employed for the limiting apparent molar volumes ( $\phi_V^0$ ), experimental slopes ( $S_V^*$ ) to interpret the solute–solvent and solute–solute interactions respectively. Molar refractions ( $R$ ) have been calculated using the Lorentz–Lorenz equation. Jones–Dole equation was used to derive parameters  $A$  and  $B$  to interpret the interactions. Limiting apparent molar adiabatic compressibilities ( $\phi_K^0$ ) at infinite dilution were examined from the sound speed values.

## 1. Introduction

Amino acids are the bioactive compounds playing central roles both as building blocks of proteins and as intermediates in metabolism. They are very much useful in food technology and industry.

Limiting apparent molar volume ( $\phi_V^0$ ), experimental slopes ( $S_V^*$ ), and viscosity  $B$ -coefficients, molar refraction ( $R$ ) and limiting apparent molar adiabatic compressibility ( $\phi_K^0$ ) of a solute reflect the cumulative effects [1–5] of the interactions like ion–ion, ion–solvent, and solvent–solvent interactions in solutions. In this paper we have attempted to study these properties for three amino acids namely glycine, L-alanine, and L-valine in aqueous Barium Nitrate solutions at 298.15 K to understand the solute–solute and solute–solvent interactions.

## 2. Experimental methods

### 2.1. Source and purity of samples

The mass fraction of purity of barium nitrate of puriss grade (Sigma–Aldrich, Germany) was  $\geq 0.99$ . It was recrystallised from aqueous Ethanol solution after being dried under vacuum at

$T=348$  K and it was stored over P<sub>2</sub>O<sub>5</sub> kept in a desiccators [6]. The three amino acids namely glycine, L-alanine and L-valine (S.D. Fine Chemicals, >99%) were taken without any further purification. Barium nitrate solution was prepared with freshly distilled conductivity water. Table 1 depicts the physical properties of different mass fraction of aqueous barium nitrate solution.

### 2.2. Apparatus and procedure

Density ( $\rho$ ) was measured with Vibrating-tube Anton Paar Density-Meter (DMA 4500 M) with a uncertainty of 0.00005 g cm<sup>-3</sup> after being calibrated by double-distilled water and dry air [7]. The temperature was kept fixed within  $\pm 0.01$  K.

Ubbelohde type viscometer was used to measure the viscosity ( $\eta$ ) whilst calibrated at 298.15 K with distilled water and pure Methanol. A thoroughly cleaned and dried viscometer containing the experimental liquid was placed vertically in a glass-walled thermostat (Bose Panda Instruments Pvt. Ltd.). The flow times were accurate to  $\pm 0.1$  s. Airtight-stopper bottles were used for the preparation of the mixtures. A triplicate measurement was taken into account with sufficient precautions to minimize the evaporation loss. A Mettler AG-285 electronic balance with a uncertainty of  $\pm 0.01$  mg was used to measure the mass. The uncertainty of density measurements was  $\pm 3 \times 10^{-4}$  g cm<sup>-3</sup>.

Viscosity of the solution is evaluated using the appropriate equation as reported earlier [8]. The uncertainty in viscosity measurements was within  $\pm 0.003$  mPa s.

**Table 1**

The values of density ( $\rho$ ), viscosity ( $\eta$ ), refractive index ( $n_D$ ), and speed of sound ( $u$ ) in different mass fraction of barium nitrate at 298.15 K and experimental pressure 0.1 MPa.

Mass-fraction of barium nitrate	<sup>a</sup> $\rho \times 10^{-3}$ (kg m <sup>-3</sup> )	<sup>b</sup> $\eta$ (mPa s)	<sup>c</sup> $n_D$	<sup>d</sup> $u$ (ms <sup>-1</sup> )
$w_1 = 0.01$	0.99737	0.904	1.3327	1512.7
$w_1 = 0.03$	0.99848	0.910	1.3334	1516.4
$w_1 = 0.05$	0.99956	0.916	1.3342	1519.3

<sup>a</sup> Uncertainty in the density values:  $\pm 0.01$  kg m<sup>-3</sup>.

<sup>b</sup> Uncertainty in the viscosity values:  $\pm 0.003$  mPa s.

<sup>c</sup> Uncertainty in the refractive index values:  $\pm 0.0002$  units.

<sup>d</sup> Uncertainty in the speed of sound:  $\pm 0.2$  m.s<sup>-1</sup>.

Refractive index was calculated by means of Digital Refractometer Mettler Toledo. The light source was LED,  $\lambda = 589.3$  nm. The calibration of refractometer was done twice using distilled water and being checked after every few measurements. The uncertainty of refractive index measurement was  $\pm 0.0002$  units.

An ultrasonic interferometer (Model M-83 from Mittal enterprises) was utilized to measure the ultrasonic velocities,  $u$  (ms<sup>-1</sup>). The interferometer (2 MHz) is based on the principle used by Freyer et al. [9] and Kiyoharo et al. [10,11]. The obtained velocities were corrected for diffraction errors as given by Subrahmayan et al. [12]. The maximum uncertainty in the velocity was  $\pm 0.5$  m s<sup>-1</sup>. The temperature control were carried out within  $\pm 0.01$  K using a Lauda thermostat for velocity measurements.

The solutions under investigation were prepared by mass and the conversion of molarity into molality was accomplished [4] from the studied density values. The experimental values of densities ( $\rho$ ), viscosities ( $\eta$ ), refractive indices ( $n_D$ ) and ultrasonic speeds ( $u$ ) of solutions are reported in Table 2 and the derived parameters are listed in Tables 3 and 4.

### 3. Results and discussion

#### 3.1. Density calculation

The determination of Apparent molar volumes ( $\phi_V$ ) were done from the solution densities using the following equation [13].

$$\phi_V = \frac{M}{\rho - 1000} \frac{(\rho - \rho_0)}{m\rho_0} \quad (1)$$

where  $M$  is the molar mass of the solute,  $m$  is the molality of the solution  $\rho_0$  and  $\rho$  are the densities of the solution and the mixture respectively. The limiting apparent molar volume  $\phi_V^0$  was obtained using a least-square treatment to the plot of  $\phi_V$  versus  $\sqrt{m}$  with the help of Masson equation [14].

$$\phi_V = \phi_V^0 + S_V^* m^{1/2} \quad (2)$$

where  $\phi_V^0$  is the limiting apparent molar volume at infinite dilution and  $S_V^*$  is the experimental slope. The plots of  $\phi_V$  against square root of molal concentration ( $\sqrt{m}$ ) were found to be linear. Values of  $\phi_V^0$  and  $S_V^*$  are reported in Table 4.

A perusal of Table 4 reveals that  $\phi_V^0$  values for amino acids are positive and increase with an increase in concentrations of aqueous barium nitrate mixture, indicating the presence of strong solute–solvent interactions and these interactions are further strengthened with the increase of the mass fraction of Ba(NO<sub>3</sub>)<sub>2</sub> in the solvent mixture. The trend in the solute–solvent interaction is

Glycine < L-alanine < L-valine

This indicates that the solute–solvent interaction increases with the increase in the number of carbon atoms in the three amino acids.

**Fig. 1.** Plots of limiting apparent molar volumes ( $\phi_V^0$ ) for glycine (—◆—), L-alanine (—■—), L-valine (—▲—) in different mass fractions ( $w_1$ ) of Ba(NO<sub>3</sub>)<sub>2</sub> in aqueous mixture at 298.15 K.

The  $S_V^*$  values of the amino acid solution (Table 4) follow a decreasing order with the increase in the number of carbon atoms of the above mentioned amino acids and also the mass fraction of barium nitrate in its aqueous mixture. Thus solute–solute interaction is minimized in the higher analogs.

The predominance of solute–solvent interactions over solute–solute interactions was cemented from the higher values of  $\phi_V^0$  than  $S_V^*$  obtained from Fig. 1. The same result was obtained for each of the studied amino acids as well as mass fraction of barium nitrate in the mixture.

#### 3.2. Viscosity calculation

The viscosity data has been analyzed using Jones–Dole equation [15]

$$\left( \frac{(\eta/\eta_0 - 1)}{m} \right)^{1/2} = A + Bm^{1/2} \quad (3)$$

where  $\eta_0$  and  $\eta$  are the viscosities of the solvent and solution respectively.  $A$  and  $B$  are the viscosity co-efficient estimated by a least-squares method and are reported in Table 4. The values of the  $A$  co-efficient are found to decrease with the increase in the number of carbon atoms of amino acids (starting from glycine to L-valine) and with the increase in mass fraction of barium nitrate in solvent mixture. The results reveal the presence of very weak solute–solute interactions. These results are in excellent agreement with those obtained from  $S_V^*$  values discussed earlier.

The effects of solute–solvent interactions on the solution viscosity can be inferred from the  $B$ -coefficient [16,17]. The viscosity  $B$ -coefficient is an important tool to provide information concerning the solvation of the solutes and their effects on the structure of the solvent. From Table 4 and Fig. 2 it is evident that the values of the  $B$ -coefficient are positive for all the amino acids and increase with the increase of the size of the side chains. This is due to the greater structure breaking tendency of L-valine as compared to L-alanine [18]. The  $B$ -coefficients reflect the net structural effects of the charged groups and the hydrophobic CH<sub>2</sub>-groups on the amino acids. Thus solute–solvent interaction predominates and increases with the increase of mass fraction of Ba(NO<sub>3</sub>)<sub>2</sub> in the solvent mixture. This observation is in a fine agreement with the results obtained from  $\phi_V^0$  values discussed earlier.

**Table 2**  
Experimental values of molality ( $m$ ), density ( $\rho$ ), viscosity ( $\eta$ ), refractive index ( $n_D$ ) and ultrasonic speed ( $u$ ) of glycine, L-alanine and L-valine in different mass fraction of barium nitrate in the solvent mixture [Ba(NO<sub>3</sub>)<sub>2</sub> + Water] at 298.15 K and experimental pressure 0.1 MPa.

### 3.3. Refractive index calculation

The molar refraction,  $R$  has been evaluated from Lorentz–Lorenz relation [19]

$$R = \left\{ \frac{(n_D^2 - 1)}{(n_D^2 + 2)} \right\} \left( \frac{M}{\rho} \right) \quad (4)$$

where  $R$ ,  $n_D$ ,  $\rho$  and  $M$  are the molar refraction, the refractive index, density and the molar mass of the solution respectively. According to Born et al. [20] the greater the refractive index of a substance, the more the light is refracted and it was further supported by Deetlefs et al. [21].

More tightly packed substance i.e. more denser solution has higher refractive index. So refractive index value rises with the increase of mass fraction of barium nitrate in solvent mixture.

**Table 3**

Molality ( $m$ ), apparent molar volume ( $\phi_V$ ),  $(\eta/\eta_0 - 1)/m^{1/2}$ , molar refraction ( $R$ ), adiabatic compressibility ( $\beta$ ) and apparent molal adiabatic compressibility ( $\phi_K$ ) of Glycine, L-Alanine and L-Valine in barium nitrate at 298.15 K and Experimental Pressure 0.1 MPa.

<sup>a</sup> Uncertainty in the molality:  $\pm 0.0001$  mol kg<sup>-1</sup>.

**Table 4**  
Limiting apparent molar volumes ( $\phi_V^0$ ), experimental slopes ( $S_V^*$ ),  $A$ ,  $B$  coefficients, limiting partial adiabatic compressibility ( $\phi_K^0$ ), and experimental slope ( $S_K^*$ ) of glycine, L-alanine, and L-valine in aqueous barium nitrate at 298.15 K and experimental pressure 0.1 MPa.

Salt	$\phi_V^0 \times 10^6$ (m <sup>3</sup> mol <sup>-1</sup> )	$S_V^* \times 10^6$ (m <sup>3</sup> mol <sup>-3/2</sup> kg <sup>1/2</sup> )	$A$ (kg mol <sup>-1</sup> )	$B$ (kg <sup>1/2</sup> mol <sup>-1/2</sup> )	$\phi_K^0 \times 10^{10}$ (m <sup>3</sup> mol <sup>-1</sup> Pa <sup>-1</sup> )	$S_K^* \times 10^4$ (m <sup>3</sup> mol <sup>-3/2</sup> Pa <sup>-1</sup> kg <sup>1/2</sup> )
$w_1 = 0.01$						
Glycine	51.53	-24.01	0.023	0.131	0.151	-27.92
L-Alanine	71.05	-36.48	0.015	0.463	0.795	-28.68
L-Valine	110.30	-60.17	0.012	0.887	1.591	-29.61
$w_1 = 0.03$						
Glycine	60.01	-40.08	0.011	0.181	0.229	-30.82
L-Alanine	82.47	-66.5	0.008	0.477	1.012	-31.46
L-Valine	119.60	-88.43	0.007	0.920	1.796	-32.35
$w_1 = 0.005$						
Glycine	61.19	-41.27	0.009	0.197	0.478	-34.82
L-Alanine	85.84	-76.71	0.007	0.478	1.215	-35.72
L-Valine	124.30	-113.10	0.006	0.931	2.012	-37.72

Hence from Tables 2 and 3 it is clear that for L-valine the refractive index and the molar refraction values are higher than the other two amino acids. Thus solute–solvent interaction predominates over solute–solute interaction. This fact also supports the results obtained from density and viscosity parameters discussed above. The studied amino acids in aqueous barium nitrate solution obey the same trend of solute–solvent interaction i.e.

Glycine < L-alanine < L-valine

### 3.4. Ultrasonic speed calculation

The adiabatic compressibility ( $\beta$ ) was evaluated with the help of the following equation:

$$\beta = \frac{1}{u^2 \rho} \quad (5)$$

where  $u$  is the sound speed in the solution and  $\rho$  is the solution density. The apparent molal adiabatic compressibility ( $\phi_K$ ) of the solutions was analyzed from the relation.

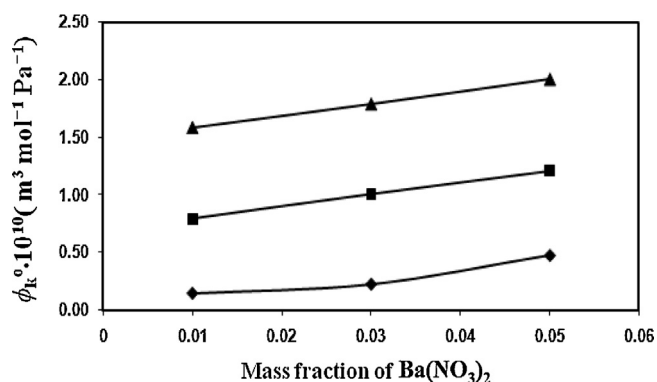

$$\phi_K = \frac{M\beta}{\rho + 1000} \frac{(\beta\rho_0 - \beta_0\rho)}{m\rho\rho_0} \quad (6)$$

where  $\beta$  and  $\beta_0$  are the adiabatic compressibility of the solution and solvent respectively and  $m$  is the molality of the solution. Limiting partial molal adiabatic compressibilities ( $\phi_K^0$ ) and experimental slopes ( $S_K^*$ ) were achieved by fitting  $\phi_K$  against the square root of molality of the electrolyte ( $\sqrt{m}$ ) using the least-squares method.

$$\phi_K = \phi_K^0 + S_K^* m^{1/2} \quad (7)$$

The values of  $\beta$  and  $\phi_K$  are enlisted in Table 3 and the values of  $\phi_K^0$  and  $S_K^*$  are presented in Table 4. The values of  $\phi_K^0$  and  $S_K^*$  also represent the extent of solute–solvent and solute–solute interactions respectively. An inspection of Table 4 and Fig. 3 confirms that the  $\phi_K^0$  values are in an excellent agreement with those drawn from the values of  $\phi_V^0$  discussed earlier.

Owing to the greater +I effect of alkyl chain in L-valine in comparison with other two studied amino acids negative charge density becomes maximum on the oxygen atom of the carboxylic part. So the solute–solvent interaction of L-valine with Ba<sup>2+</sup> ion is highest among the three and thereby supporting the order of interactions mentioned above.

**Fig. 3.** Plots of limiting partial adiabatic compressibility ( $\phi_K^0$ ) for glycine (—◆—) L-alanine (—■—), L-valine (—▲—) in different mass fractions ( $w_1$ ) of Ba(NO<sub>3</sub>)<sub>2</sub> in aqueous mixture at 298.15 K.

## 4. Conclusions

The values of the limiting apparent molar volume ( $\phi_V^0$ ), viscosity  $B$ -coefficients and limiting partial isentropic compressibility ( $\phi_K^0$ ) indicate the presence of strong solute–solvent interactions which increases with the increase in the number of carbon atoms of the amino acids and also with the increase of mass fraction of barium nitrate in the aqueous mixture. The refractive index and the molar refraction values indicate that molecules of L-valine are more tightly packed in the solution resulting higher solute–solvent interaction than the other two amino acids.

## Acknowledgements

The authors are grateful to the UGC supported Major research project, Ref. No. RP/5032/FCS/2011 New Delhi for financial support in order to continue this research work.

One of the authors, Prof. M. N. Roy is thankful to University Grant Commission, New Delhi, Government of India for being awarded one time grant under Basic Scientific Research via the grant-in-Aid No. F.4-10/2010 (BSR) regarding his active service for augmenting of research facilities to facilitate further research work.
