HIGHLIGHTS

• IR, Raman, NBO analysis and MEP were reported.

- The wavenumbers are calculated theoretically using Gaussian09 software.
- The wavenumbers are assigned using PED analysis.
- The geometrical parameters are in agreement with the reported literature.

G R A P H I C A L A B S T R A C T

In this work, the vibrational spectral analysis was carried out using FT-IR and FT-Raman spectroscopy for 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid. The computations were performed at HF and DFT levels of theory to get the optimized geometry and vibrational wavenumbers of the normal modes of the title compound. The complete vibrational assignments of wavenumbers were made on the basis of potential energy distribution and using Gaussview software. The calculated HOMO and LUMO energies show the chemical activity of the molecule. The stability of the molecule arising from hyper-conjugative interaction and charge delocalization has been analyzed using NBO analysis. The calculated geometrical parameters are in agreement with that of similar derivatives. The stability of the molecule arising from hyper-conjugative interaction and charge delocalization has been analyzed using NBO analysis.

ABSTRACT

Quinoline derivatives have good nonlinear optical properties and have been extensively studied due to their great potential application in the field of organic light emitting diodes. Quantum chemical calculations of the equilibrium geometry, harmonic vibrational frequencies, infrared intensities and Raman activities of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid in the ground state were reported. Potential energy distribution of normal modes of vibrations was done using GAR2PED program. The synthesis, ¹H NMR and PES scan results are also discussed. Nonlinear optical behavior of the examined molecule was investigated by the determination of first hyperpolarizability. The calculated HOMO and LUMO energies show the chemical activity of the molecule. The stability of the molecule arising from

Introduction

Quinoline derivatives possess non-centro symmetry and hence they are used in the synthesis of molecules having non-linear responses [1,2]. Some quinoline derivatives have good nonlinear optical properties [3,4] and have been extensively studied due to their great potential application in the field of organic light emitting diodes (OLED) [5-16]. Quinolines have good electron mobility, good thermal and oxidative stabilities, high photoluminescence efficiency and good film forming properties which is important for their use in OLEDs [17,18]. Certain derivatives extracted from the plant Camptotheca acuminata have been a potential anticancer drug. Its inhibition completely blocks the cell proliferation and hence the cancer growth and has shown their anticancer activity against a wide spectrum of human malignancies, including, lung, prostrate, breast, colon, stomach, ovaries, carcinomas, melanoma, lymphomas and sarcomas [19-21]. Quinoline derivatives are well known for its anti-malarial, antifungal and anti-amoebic activities [22]. In addition to the medical applications, these derivatives can function as, pesticides, corrosion inhibitors and components in photographic, digital recording devices and fabric dyes [23]. In the present work, IR and Raman spectra of the title compound are reported both experimentally and theoretically. Also the NBO analysis, molecular electrostatic potential, NMR studies and first hyperpolarizability is also reported.

Experimental details

The synthesis of the quinoline derivative was done by [24] adding corresponding anilines (0.20 ml) and malonic acid (0.18 mol). Naphthalene (0.12 mol) and malonic acid (0.18 mol) were melted under stirring at temperature control (<150 °C) to avoid decarboxylation of the acid. POCl₃ (0.36 mol) was then added dropwise over 30 min and aminosalicylic acid (0.1 mol) was then added. The resulting mixture was heated for 30 min and allowed to cool. Water (100 ml) was added to the warm mixture and the solution was alkalized with 20% NaOH to pH 9. After cooling on ice precipitated naphthalene, it was filtered and the filtrate was acidified to pH 2. The product was filtered again and crystallized from acetic acid.

The FT-IR spectrum (Fig. 1) was recorded using KBr pellets on a DR/Jasco FT-IR 6300 spectrometer. The FT-Raman spectrum (Fig. 2) was obtained on a Bruker RFS 100/s, Germany. For excitation of the spectrum the emission of Nd:YAG laser was used, excitation wavelength 1064 nm, maximal power 150 mW, measurement on solid sample. 1 H NMR spectra was recorded on a Bruker AM-500 (500 MHz for 1 H), Bruker BioSpin Corp., Germany. Chemicals shifts are reported in ppm (δ) to internal Si (CH₃)₄, when diffused easily exchangeable signals are omitted.

Computational details

Calculations of the title compound are carried out with Gaussian09 program [25] using the HF/6-31G*, B3LYP/6-31G* and B3LYP/SDD quantum chemical calculation methods to predict the molecular structure and vibrational wave numbers. Molecular geometry was fully optimized by Berny's optimization algorithm using redundant internal coordinates. Harmonic vibrational wave numbers are calculated using the analytic second derivatives to

Fig. 1. FT-IR spectrum of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

Fig. 2. FT-Raman spectrum of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

confirm the convergence to minima on the potential surface. The wave number values computed at the Hartree–Fock level contain known systematic errors due to the negligence of electron correlation. We therefore, have used the scaling factor value of 0.8929 for HF method. The DFT hybrid B3LYP functional and SDD methods tend to overestimate the fundamental modes, therefore scaling factor of 0.9613 has to be used for obtaining a considerably better agreement with experimental data [26]. The Stuttgart/Dresden effective core potential basis set (SDD) was chosen particularly

Fig. 3. Optimized geometry (SDD) of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

because of its advantage of doing faster calculations with relatively better accuracy and structures [27,28]. Then frequency calculations

were employed to confirm the structure as minimum points in energy. Parameters corresponding to optimized geometry (SDD) of the title compound (Fig. 3) are given in Table 1. The absence of imaginary wavenumbers on the calculated vibrational spectrum confirms that the structure deduced corresponds to minimum energy. The assignments of the calculated wave numbers are aided by the animation option of GAUSSVIEW program, which gives a visual presentation of the vibrational modes [29]. The potential energy distribution (PED) is calculated with the help of GAR2PED software package [30].

Results and discussion

IR and Raman spectra

The observed IR and Raman bands and calculated (scaled) wavenumbers and assignments are given in Table 2. The NH stretching vibrations give rise to bands at 3500–3300 cm⁻¹ [31,32]. In the present study the bands observed at 3430 cm⁻¹ in

v-stretching; δ -in-plane deformation; γ -out-of-plane deformation; τ -twisting; Ph-Phenyl ring; Ring-quinoline ring; In the assignment column the potential energy distributions are given in brackets.

IR, 3469 cm⁻¹ in Raman and 3468 cm⁻¹ (SDD) are assigned as NH stretching vibrations. N—H group show bands at 1510–1500, 1350–1250 and 740–730 cm⁻¹ [33]. According to literature, if N—H is a part of a closed ring [32,33] the C—N—H deformation band is absent in the region 1510–1500 cm⁻¹. For the title compound the C—N—H deformation band is observed at 1366 cm⁻¹ in the Raman spectrum, 1376 cm⁻¹ in the IR spectrum and at

1368 cm⁻¹ theoretically. The out of plane NH deformation is expected in the region 650 ± 50 cm⁻¹ [34] and bands at 726 cm⁻¹ in Raman and 735 cm⁻¹ in SDD are assigned as this mode. Minitha et al. [35] reports vNH at 3469 cm⁻¹, δ NH at 1300 cm⁻¹ and γ NH at 535 cm⁻¹. Panicker et al. reported the out-of-plane bending mode of NH at 746 cm⁻¹, theoretically [36]. The CN stretching modes are expected [37] in the range 1100–1300 cm⁻¹. The bands observed at

1262 cm⁻¹ in IR, 1202 cm⁻¹ in Raman and at 1270, 1230 cm⁻¹ theoretically (SDD) are assigned as CN stretching modes. Panicker et.al reported the CN stretching mode at 1215 cm⁻¹ theoretically [36].

According to Socrates [33] the C=C stretching is expected around $1600 \, \mathrm{cm^{-1}}$ when conjugated with C=O. The C_{20} = O_{22} and C_{15} = C_{18} stretching bands are assigned at 1627 (SDD), 1610 cm⁻¹ (IR), $1609 \, \mathrm{cm^{-1}}$ (Raman) and at $1607 \, \mathrm{cm^{-1}}$ (SDD), $1610 \, \mathrm{cm^{-1}}$ (IR), $1609 \, \mathrm{cm^{-1}}$ (Raman), respectively. The deformation bands of C=O and C=C are also identified and assigned (Table 2).

The carboxylic group is characterized by the OH stretch, C=O stretch and OH out-of-plane deformation and even by the C-O stretch and OH in-plane deformation. The C=O stretching vibration in the spectra of carboxylic acids give rise to a strong band in the region $1600-1700 \text{ cm}^{-1}$ [34]. The band observed at 1651 cm^{-1} in the IR spectrum1652 cm⁻¹ in the Raman spectrum and at 1634 cm⁻¹ (SDD) is assigned as C=O stretching mode. The OH inplane deformation, coupled to the C-O stretching mode is expected in the region $1390 \pm 55 \text{ cm}^{-1}$ [34], and the band at 1262 cm⁻¹ (IR), 1270 cm⁻¹ (SDD) is assigned as the in-plane bending of OH group which is not pure but contains contributions from other modes also. The C(=0)O stretching mode coupled to OH inplane bending exhibits a band in the region $1250 \pm 80 \text{ cm}^{-1}$ and the SDD calculation give C-O stretching mode at 1313 cm⁻¹. Experimentally bands are observed at 1298 cm⁻¹ in the IR spectrum and at 1319 cm⁻¹ in the Raman spectrum. The deformation bands, out-of-plane OH, in-plane C=O and out-of-plane C=O are expected in the regions, 905 ± 65 , 725 ± 95 and 595 ± 85 cm⁻¹, respectively [34]. These bands are assigned at 913 cm⁻¹ (Raman), 926 (SDD), and 755 (IR), 752 (Raman), 766 cm⁻¹ (SDD) and 703 (IR), 706 (Raman), 719 cm $^{-1}$ (SDD) respectively. The -C(=0)O rocking mode is expected in the region $445 \pm 120 \, \text{cm}^{-1}$ [34], and in the present case the SDD calculations give this mode at 476 cm⁻¹. Varghese et al., [38] reported COOH deformation bands at 785 cm⁻¹ and 378 cm⁻¹.

For the hydroxyl group, the OH group provides three normal vibrations; the stretching vibration OH, in-plane and out-of-plane deformations δ OH and γ OH. The in-plane OH deformation [34] is expected in the region1440 \pm 40 cm $^{-1}$ and the band at 1409 in Raman spectrum and at 1412 cm $^{-1}$ (SDD) is assigned as this mode. The stretching of hydroxyl group C—O appears at 1214 cm $^{-1}$ in the IR spectrum and the calculated value is 1206 cm $^{-1}$ (SDD) and this band is not pure, but contains significant contributions from other modes also. This band is expected in the region $1220\pm40~{\rm cm}^{-1}$ [39–41]. The out-of-plane deformation is expected generally in the region $650\pm80~{\rm cm}^{-1}$ [34] and in the present case it is assigned at $636~{\rm cm}^{-1}$ theoretically (SDD). For paracetamol, the C—O stretching mode and out-of-plane OH are reported at 1240 and $620~{\rm cm}^{-1}$, respectively [42]. The SDD calculations give OH stretching at $3563~{\rm cm}^{-1}$.

Aromatic compounds commonly exhibit multiple weak bands in the region 3100–3000 cm $^{-1}$, due to aromatic CH stretching vibrations [34]. However, these bands are rarely useful because they overlap with one another resulting in stronger absorption in this region. The SDD calculations give the CH stretching modes of the phenyl ring at 3138, 3117, 3094 cm $^{-1}$. The bands observed at 3077 cm $^{-1}$ in the IR spectrum and at 3126, 3077 cm $^{-1}$ in the Raman spectrum are assigned as CH stretching modes of the phenyl ring. For the title compound, the bands at 1118 (IR), 1113, 1240 (Raman) and 1120, 1130, 1247 cm $^{-1}$ (SDD) are assigned as the CH in-plane bending modes of the phenyl ring. The CH out-of-plane deformations are expected below 1000 cm $^{-1}$ [34] and for the title compound, the SDD calculations give bands at 947, 897 and 869 cm $^{-1}$ as γ CH modes. Experimentally bands are observed at 900 cm $^{-1}$ in the IR spectrum and at 947, 885 cm $^{-1}$ in the Raman spectrum.

The benzene ring possesses six ring stretching modes of which the four with the highest wavenumbers occurring near 1600, 1580, 1490 and 1440 cm⁻¹ are good group vibrations [34]. The bands observed at 1590, 1540, 1486, 1445, 1376 cm⁻¹ in the IR spectrum, 1537, 1488, 1445, 1366 cm⁻¹ in the Raman spectrum and at 1578, 1535, 1491, 1433, 1368, 1340 cm⁻¹ theoretically (SDD) are assigned as phenyl ring stretching modes. These modes are expected in the region 1250–1620 cm⁻¹ [34]. In the case of tri-substituted benzenes, with mixed substituent, the ring breathing mode is expected in the range 600–750 cm⁻¹ [40] and in the present case, the band observed at 788 cm⁻¹ in the Raman spectrum and at 769 cm⁻¹ (SDD) is assigned as the ring breathing mode of the phenyl ring. Mary et al., [43] reported the ring breathing mode of the tri-substituted benzene ring at 738 cm⁻¹.

In the present case, the quinoline ring modes are observed at 1610, 1445, 1020 (CC stretching modes), 1262 (CN stretch) in IR, 1609, 1051, 1022 (CC stretching modes), 1202 (CN stretch) in Raman, 1607, 1433, 1045, 1035 (CC stretching modes), 1270, 1230 cm⁻¹ (CN stretch) theoretically (SDD). For the title compound, the in-plane vibrations of the quinoline ring are observed at 519 cm⁻¹ in IR, 500, 422 cm⁻¹ in Raman and 528, 435 cm⁻¹ in SDD. The torsional modes are seen at 285, 216 cm⁻¹, in Raman and 285, 225 cm⁻¹ in SDD. The other deformations modes of the phenyl and quinoline ring are also identified and assigned (Table 2). The in plane bending of quinoline ring is reported by Chowdhury et al. [44] at 526, 472, 508, 624, 829, 869 cm⁻¹ and the ring vibrations at 1245, 1383, 1434, 1470, 1593, 1621 cm⁻¹ in the Raman spectrum and 760 cm⁻¹ as the ring breathing mode. Krishnakumar et al. reported the out of plane bending of quinoline derivatives at 586, 601, 634, 505, 538, 612 cm⁻¹ theoretically [45]. The substituent sensitive modes of the rings are also identified and assigned (Table 2).

Optimized geometrical parameters

To best of our knowledge, no X-ray crystallographic data of the title compound have yet been reported. However, the theoretical results (SDD) obtained are almost comparable with the reported structural parameters of similar derivates. For the title compound the bond length of C_5 — C_6 is observed as 1.4092 Å and this length is greater than that of C_4 — C_5 (1.3860 Å) because of the delocalisation of electron density of C_5 — C_6 due to the presence of C=O group. The $C_{15}=C_{18}$ could be assumed a double bond character due to the lesser bond length 1.3608 Å. The greater bond length of C₁—C₂ (1.4020 Å) is due to delocalisation of electron density due to the adjacent quinoline ring. It has been reported that the bond lengths of C_1-C_2 is 1.4188 Å, C_5-C_6 is 1.415 Å and $C_{15}=C_{18}$ is 1.3679 Å [46]. The bond angle $C_1-C_2-C_3$ (119.6°) and $C_2-C_3-C_4$ (119.4°) is lesser than 120° because of the presence of quinoline ring. The angles C2-N14-C20 and C3-C15-C18 are 125.8 and 121.3° respectively, which can be assumed as due to the presence of OH group which is electropositive. The presence of higher electronegative group C=O would be the reason for the greater bond angle of N₁₄--C₂₀-C₁₈ (114.2°). Yurdakul and Yurdakul reported the bond angles as $C_1-C_2-C_3$ (118.9), $C_2-C_3-C_4$ (119.3), $C_2-N_{14}-C_{20}$ (118.93), $C_3 - C_{15} - C_{18}$ (119.85), $N_{14} - C_{20} - C_{18}$ (122.82) [46]. The C₁₀=O₁₂ group is slightly tilted from the tri-substituted phenyl ring as evident from the dihedral angle C_1 — C_6 — C_{10} — O_{11} = -19.9° .

HOMO and LUMO

HOMO (Highest Occupied Molecular Orbital) and LUMO (Lowest Unoccupied Molecular Orbital) are the very important parameters for quantum chemistry. The conjugated molecules are characterized by a HOMO-LUMO separation, which is the result of a significant degree of ICT (Intra-molecular Charge Transfer) from the end-capping electron-donor groups to the efficient electron-acceptor groups through π -conjugated path. The strong

charge transfer interaction through π -conjugated bridge results in substantial ground state donor–acceptor mixing and the appearance of a charge transfer band in the electronic absorption spectrum. The atomic orbital components of the frontier molecular orbitals are shown in Figs. 4 and 5. The HOMO–LUMO gap is found to be 3.073 eV.

Molecular electrostatic potential (MEP)

MEP is related to the ED and is a very useful descriptor in understanding sites for electrophilic and nucleophilic reactions as well as hydrogen bonding interactions [47,48]. The electrostatic potential V(r) is also well suited for analyzing processes based on the "recognition" of one molecule by another, as in drug-receptor, and enzyme–substrate interactions, because it is through their potentials that the two species first "see" each other [49,50]. To predict reactive sites of electrophilic and nucleophilic attacks for the investigated molecule, MEP at the B3LYP/6-31G(d,p) optimized geometry was calculated. The negative (red and yellow) regions of MEP were related to electrophilic reactivity and the positive (blue) regions to nucleophilic reactivity (Fig. 6). The C=O group is observed as electrophilic.

NBO analysis

The natural bond orbitals (NBO) calculations were performed using NBO 3.1 program [51] as implemented in the Gaussian09 package at the DFT/B3LYP level in order to understand various second-order interactions between the filled orbitals of one subsystem and vacant orbitals of another subsystem, which is a measure of the intermolecular delocalization or hyper conjugation. NBO analysis provides the most accurate possible 'natural Lewis structure' picture of 'j' because all orbital details are mathematically chosen to include the highest possible percentage of the electron density. A useful aspect of the NBO method is that it gives information about interactions of both filled and virtual orbital spaces that could enhance the analysis of intra and inter molecular interactions. The second-order Fock-matrix was carried out to evaluate the donor-acceptor interactions in the NBO basis. The interactions result in a loss of occupancy from the localized NBO of the idealized Lewis structure into an empty non-Lewis orbital. For each donor (i) and acceptor (j) the stabilization energy (E2) associated with the delocalization $i \rightarrow j$ is determined as

$$E(2) = \Delta E_{ij} = q_i \frac{(F_{i,j})^2}{(E_i - E_i)}$$

 q_i is donor orbital occupancy, E_i , E_j is the diagonal elements, and F_{ij} is the off diagonal NBO Fock matrix element.

Fig. 4. HOMO plot of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

Fig. 5. LUMO plot of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

Fig. 6. MEP plot of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

In NBO analysis large E(2) value shows the intensive interaction between electron-donors and electron- acceptors, and greater the extent of conjugation of the whole system, the possible intensive interaction are given in Table 3. The second-order perturbation theory analysis of Fock-matrix in NBO basis shows strong intermolecular hyper conjugative interactions are formed by orbital overlap between n(O), n(N) and $\sigma^*(N-C)$, $\pi^*(C-C)$, σ^*C-O , $\pi^*(C-O)$,bond orbitals which result in ICT causing stabilization of the system. These interactions are observed as an increase in electron density (ED) in N-C, C-O and C-C anti bonding orbital that weakens the respective bonds. There occurs a strong inter molecular hyper conjugative interaction of N_{14} – C_{20} from O_{22} of $n_2(O_{22}) \rightarrow \sigma^*(N_{14}-C_{20})$ which increases ED(0.08934e) that weakens the respective bonds N₁₄—C₂₀ leading to stabilization of 29.22 kJ/mol and also the hyper conjugative interaction of C_{15} — C_{18} from O_{16} of $n_2(O_{16}) \rightarrow$ $\pi^*(C_{15}\!-\!C_{18})$ which increases ED (0.24448e) that weakens the respective bonds C₁₅—C₁₈ leading to stabilization of 33.85 kJ/mol. There occurs a strong inter molecular hyper conjugative interaction of C_{20} — O_{22} from N_{14} of $n_1(N_{14}) \rightarrow \pi^*(C_{20}$ — $O_{22})$ which increases ED (0.3452e) that weakens the respective bonds C_{20} – O_{22} leading to stabilization of 52.08KJ/mol and also the hyper conjugative interaction of $C_{10}\text{--}O_{11}$ from O_{12} of $n_2(O_{12})\to \sigma^*(C_{10}\text{--}O_{11})$ which increases ED (0.09893e) that weakens the respective bonds C_{10} — O_{11} leading to stabilization of 34.4 kJ/mol. Again a hyper conjugative interaction of C_{10} — O_{12} from O_{11} of $n_2(O_{11}) \to \pi^*(C_{10}$ — $O_{12})$ which increases ED (0.2263e) that weakens the respective bonds C_{10} — O_{12} leading to stabilization of 39.15 kJ/mol. These interactions are observed as an increase in electron density (ED) in N-C, C-C and C-O anti bonding orbitals that weakens the respective bonds.

The increased electron density at the oxygen atoms leads to the elongation of respective bond length and a lowering of the corresponding stretching wave number. The electron density (ED) is transferred from the n(O) to the anti-bonding π^* orbital of the

Table 3 Second-order perturbation theory analysis of Fock matrix in NBO basis corresponding to the intra molecular bonds of the title compound.

Donor(i)	Type	ED/e	Acceptor(j)	Type	ED/e	$E(2)^{a}$	$E(j)-E(i)^{b}$	$F(ij)^{c}$

^a E(2) means energy of hyperconjugative interactions (stabilization energy).

^b Energy difference between donor and acceptor i and j NBO orbitals.

^c F(i,j) is the Fock matrix element between i and j NBO orbitals.

N—C, C—C and C—O bonds, explaining both the elongation and the red shift [52]. The hyper conjugative interaction energy was deduced from the second-order perturbation approach. Delocalization of electron density between occupied Lewis-type (bond or lone pair) NBO orbitals and formally unoccupied (anti bond or Rydberg) non-Lewis NBO orbitals corresponds to a stabilizing donoracceptor interaction. The COOH, C=O and OH stretching modes can be used as a good probe for evaluating the bonding configuration around the atoms and the electronic distribution in the ring. Hence the structure 4-hydroxy-2-oxo-1, 2dihydroquinoline-7-car-boxylic acid is stabilized by these orbital interactions.

The NBO analysis also describes the bonding in terms of the natural hybrid orbital n₂(O₁₁), which occupy a higher energy orbital (-0.33875a.u) with considerable p-character (99.62%) and low occupation number (1.82419) and the other $n_1(O_{11})$ occupy a lower energy orbital (-0.60542a.u.) with p-character (55.88%) and high occupation number (1.97587). The NBO analysis also describes the bonding in terms of the natural hybrid orbital $n_2(O_{12})$, which occupy a higher energy orbital (-0.25807 a.u) with considerable p-character (99.68%) and low occupation number (1.84101) and the other $n_1(O_{12})$ occupy a lower energy orbital (-0.68592 a.u) with p-character (41.90%) and high occupation number (1.97824). The NBO analysis also describes the bonding in terms of the natural hybrid orbital $n_2(O_{16})$, which occupy a higher energy orbital (-0.34868 a.u) with considerable p-character (99.88%) and low occupation number (1.85418) and the other $n_1(O_{16})$ occupy a lower energy orbital (-0.62307a.u) with p-character (55.87%) and high occupation number (1.9778). The NBO analysis also describes the bonding in terms of the natural hybrid orbital $n_2(O_{22})$, which occupy a higher energy orbital (-0.23775 a.u) with considerable p-character (99.76%) and low occupation number (1.85859) and the other $n_1(O_{22})$ occupy a lower energy orbital(-0.66943a.u) with p-character (40.70%) and high occupation number (1.97692). Thus, a very close to pure p-type lone pair orbital participates in the electron donation to the σ *(N₁₄–C₂₀) orbital for n₂(O₂₂) \rightarrow - $\sigma^*(N_{14}$ — $C_{20})$, $\pi^*(C_{15}$ — $C_{18})$ orbital for $n_2(O_{16}) \to \pi^*(C_{15}$ — $C_{18})$, $\pi^*(C_{10}$ $-O_{11}$) orbital for $n_2(O_{12}) \to \pi^*(C_{10}-O_{11})$ and $\pi^*(C_{10}-O_{12})$ orbital for $n_2(O_{11}) \rightarrow \pi^*(C_{10}-O_{12})$ interaction in the compound. The results are tabulated in Table 4.

First hyperpolarizability

Nonlinear optics deals with the interaction of applied electromagnetic fields in various materials to generate new electromagnetic fields, altered in wavenumber, phase, or other physical properties [53]. Organic molecules able to manipulate photonic signals efficiently are of importance in technologies such as optical communication, optical computing, and dynamic image processing [54,55]. In this context, the dynamic first hyperpolarizability of the title compound is also calculated in the present study. The first hyperpolarizability (β_0) of this novel molecular system is calculated using SDD method, based on the finite field approach. In the presence of an applied electric field, the energy of a system is a function of the electric field. First hyperpolarizability is a third rank tensor that can be described by a $3 \times 3 \times 3$ matrix. The 27 components of the 3D matrix can be reduced to 10 components due to the Kleinman symmetry [56]. The components of β are defined as the coefficients in the Taylor series expansion of the energy in the external electric field. When the electric field is weak and homogeneous, this expansion becomes

$$E=E_0-\sum_i \mu_i F^i-\frac{1}{2}\sum_{ij}\alpha_{ij}F^iF^j-\frac{1}{6}\sum_{ijk}\beta_{ijk}F^iF^jF^k-\frac{1}{24}\sum_{ijkl}\gamma_{ijkl}F^iF^jF^kF^l$$

where E_0 is the energy of the unperturbed molecule, F^i is the field at the origin, μ_{ij} , α_{ij} , β_{ijk} and γ_{ijkl} are the components of dipole moment,

Table 4NBO results showing the formation of Lewis and non-Lewis orbitals.

polarizability, the first hyperpolarizabilities, and second hyperpolarizabilities, respectively. The calculated first hyperpolarizability of the title compound is 6.37×10^{-30} e.s.u which is 49 times that of standard NLO material urea $(0.13 \times 10^{-30}$ e.s.u) [57]. The reported values of hyperpolarizability of similar derivatives are 2.24×10^{-30} e.s.u [58] and 2.24×10^{-30} e.s.u [59].

Mulliken charges

The calculation of atomic charges plays an important role in the application of quantum mechanical calculations to molecular systems. Mulliken charges are calculated by determining the electron population of each atom as defined in the basis functions. The

charge distributions calculated by the Mulliken [60] and NBO methods for the equilibrium geometry of 4-hydroxy-2-oxo-1,2dihydroquinoline-7-carboxylic acid are given in Table 5. The charge distribution on the molecule has an important influence on the vibrational spectra. In 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid, the distribution of Mulliken atomic charge shows the direction of delocalization and shows that the natural atomic charges are more sensitive to the changes in the molecular structure than Mulliken's net charges. Also we have done a comparison of Mulliken charges obtained by different basic sets and tabulated it in Table 6 in order to assess the sensitivity of the calculated charges to changes in (i) the choice of the basis set; (ii) the choice of the quantum mechanical method. The results can, however, better be represented in graphical form as shown in Fig. 7. We have observed a change in the charge distribution by changing different basis sets.

Fig. 7. Comparison of different methods for calculated Mulliken charges of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

PES scan studies

A detailed potential energy surface (PES) scan on dihedral angles C_{10} — C_6 — C_1 — C_2 and O_{11} — C_{10} — C_6 — C_1 have been performed at B3LYP/6-31G(d) level to reveal all possible conformations of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid. The PES scan was carried out by minimizing the potential energy in all geometrical parameters by changing the torsion angle at every 10° for 180° rotation around the bond. The results obtained in PES scan study by varying the torsion perturbation around C=O are plotted in Figs. 8 and 9. For the C_{10} — C_6 — C_1 — C_2 rotation, the minimum energy was obtained at -179.0° in the potential energy curve of energy -740.7352 Hartrees. For the O_{11} — C_{10} — C_6 — C_1 rotation, the minimum energy occurs at -19.9° in the potential energy curve of energy -740.8471 Hartrees.

¹H NMR spectrum

With TMS as internal standard, experimental spectrum data of 4-hydroxy-2-oxo-1,2 dihydroquinoline-7-carboxylic acid in DMSO is obtained at 500 MHz and is shown in Table 7. B3LYP/GIAO was used to calculate the absolute isotropic chemical shielding of 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid [61]. Relative chemical shifts were then estimated by using the corresponding TMS shielding: $\sigma_{\rm calc}$ (TMS) calculated in advance at the same theoretical level as this paper. Numerical values of chemical shift

Fig. 8. Profile of potential energy scan for the torsion angle C10—C6—C1—C2.

Fig. 9. Profile of potential energy scan for the torsion angle O11—C10—C6—C1.

Table 7 Experimental and calculated ¹H NMR parameters (with respect to TMS).

Protons	σ_{TMS}	B3LYP/6-31G	$\delta_{\rm calc}$ = $\sigma_{\rm TMS} - \sigma_{\rm calc}$	Exp $\delta_{\rm ppm}$
H7	32.7711	24.8333	7.9378	8.03
H8		24.3405	8.4306	8.2
H9		25.2337	7.5374	8.2
H13		24.0689	6.7022	5.9
H17		26.2989	6.4722	5.9
H19		26.7591	6.0120	5.6
H21		24.9210	7.8501	7.8

 $\delta_{\rm pred}$ = $\sigma_{\rm calc}$ (TMS) – $\sigma_{\rm calc}$ together with calculated values of $\sigma_{\rm calc}$ (TMS), are reported in Table 7. It is seen that chemical shift was in agreement with the experimental ¹H NMR data. Thus, the results has shown that the predicted proton chemical shifts were in good agreement with the experimental data for 4-hydroxy-2-oxo-1,2-dihydroquinoline-7-carboxylic acid.

Conclusion

The vibrational spectroscopic studies of 4-hydroxy-2-oxo-1,2dihydroquinoline-7-carboxylic acid in the ground state were reported experimentally and theoretically. Potential energy distribution of normal modes of vibrations was done using GAR2PED program. The ring stretching modes in IR and Raman spectra are evidence for charge transfer interaction between the donor and the acceptor group through the π system. This along with the lowering of HOMO-LUMO band gap supports for the bioactivity of the molecule. NBO analysis predicts a strong inter molecular hyper conjugative interaction of $(N_{14}-C_{20})$ from O_{22} of $n_2(O_{22})$, $(C_{15}-C_{18})$ from O_{16} of $n_2(O_{16})$ $(C_{10}-O_{11})$ from O_{12} of $n_2(O_{12})$ and $(C_{10}-O_{12})$ from O_{11} of O_{12} of O_{11} . MEP predicts the most reactive part in the molecule. The calculated first hyperpolarizability is comparable with the reported values of similar derivatives and is an attractive object for future studies in nonlinear optics. The minimum energy surfaces are obtained from the potential energy curve by PES scan studies. In addition the calculated ¹H NMR results are in good agreement with experimental data.
